CC 8 (Radiation Biochemistry)
AB BACKGROUND: Pancreatic cancer remains the most lethal of all common human malignancies with a 5-yr survival rate of lower than 5%. Adjuvant and neoadjuvant preoperative and postoperative chemo-radiotherapy using 5-fluorouracil, have reduced local relapse rate and slightly increased the median survival. Testing new and more potent radiation-sensitizing drugs in human pancreatic cancer cells can provide the basis for a more effective chemo-radiation regimen and may consequently improve treatment outcome. MATERIALS & METHODS: The present study was performed to evaluate the efficacy of two potent ribonucleotide reductase (RR) inhibitors: hydroxyurea and ***trimidox*** in radio-sensitizing Panc-1 human pancreatic cancer cells in an attempt to identify a more effective chemo-radiotherapy regimen with minimal side effects. RESULTS: Treatment of Panc-1 cells with hydroxyurea or ***trimidox*** alone for 2 h was assocd. with a dose-dependent decrease in their cloning efficacy to similar extent. The IC50 of ***trimidox*** , hydroxyurea or radiation alone were 2.5 + 0.3 .mu.M, 39.0 + 0.4 .mu.M and 3.2 + 0.2 Gy, resp. Treatment with 39.0 microM non-cytotoxic IC50 dose of hydroxyurea for two hours before or immediately after radiation reduced the IC50 of radiation to only 1.1 + 0.14 or 1.0 + 0.1 Gy, resp. Treatment with 2.5 microM non-cytotoxic IC50 dose of ***trimidox*** for two hours before or immediately after radiation reduced the IC50 of radiation to only 1.2 + 0.16 or 1.4 + 0.12 Gy, resp. The mean radiation enhancement ratios were 2.9 and 3.2 for hydroxyurea before and immediately after radiation. The greater radio-sensitizing effect of hydroxyurea compared to ***trimidox*** or gemcitabine could be due to its unique double action by synchronising the cancer cells into the radiosensitive G1/S border and inhibiting DNA damage repair. CONCLUSIONS: The present study demonstrates the superiority of hydroxyurea at non-cytotoxic doses compared to the other two recent RR inhibitors: gemcitabine and ***trimidox*** in radio-sensitizing human pancreatic cancer cells. Hydroxyurea combined with radiation has significantly improved progression-free survival of advanced cervical cancer and glioblastoma patients and showed clin. benefit in combination with other chemotherapy drugs in advanced pancreatic cancer. The present results suggest the clin. use of hydroxyurea as a radiosensitizer in both pre- and post-operative chemo-radiotherapy in pancreatic cancer patients. Given the demonstrated potent radio-sensitizing effect of hydroxyurea at non-cytotoxic doses when administered before or immediately after radiation and its low clin. toxicity, it sould be feasible to administer hydroxyurea both before and after radiation in pancreatic cancer patients.

CC 1 (Pharmacology)
AB Upon appropriate drug treatment, the human erythroleukemic K562 cells have been shown to produce Hb and F-cells. Fetal Hb (Hb F) inhibits the polymn. events of sickle Hb (Hb S), thereby ameliorating the clin. symptoms of sickle cell disease. Ribonucleotide reductase inhibitors (RRIs) have been shown to inhibit the growth of myeloid leukemia cells leading to the prodn. of Hb F upon differentiation. Of the RRIs currently in use, hydroxyurea is the most effective agent for Hb F induction. We have examd. the capacity of two novel RRIs, didox (DI) and ***trimidox*** (TRI), in combination with streptozotocin (STZ), to induce Hb and F-cell prodn. The K562 cells were cultured with different concns. of didox-STZ or ***trimidox*** -STZ at a fixed molar ratio of 3:1 and 1:5 for 96 h, resp. At pre-detd. time intervals, aliquots of cells were obtained and total Hb (benzidine pos.) levels, no. of F-cells, and Hb F were detd. by the differential staining technique, fetal Hb assay kit, and fluorescence cytometry resp. The effect of combined drug treatment on the growth of K562 cells was examd. by isobologram anal. Our results indicate that a synergistic growth-inhibitory differentiation effect occurred when didox or ***trimidox*** was used in combination with STZ on K562 cells. There was an increase in the no. of both benzidine-pos. normoblasts and F-cells, accompanied by morphol. appearances typical of erythroid maturation. On day 4, the no. of benzidine-pos. cells showed a 6-9-fold increase and the no. of F-cells was between 2.5- and 5.7-fold higher than the resp. controls. Based upon these results, treatment with a ribonucleotide reductase inhibitor, such as didox or ***trimidox*** , in combination with STZ, might offer an addnl. promising option in sickle cell disease therapy.

AB The short-term hematopoietic toxicity of the ribonucleotide reductase inhibitor hydroxyurea (HU) was studied in mice in comparison with that of the more potent enzyme inhibitors didox (DX) and ***trimidox*** (TX). High-dose HU, DX, and TX monotherapy (500, 460, and 220 mg/kg/day, resp.) was administered by daily i.p. injection (Monday-Friday) to C57BL/6 mice for 10 wk. Effects on hematopoiesis were established by quantitating peripheral blood indexes and nos. of colony-forming units-granulocyte-macrophage (CFU-GM) and BFU-E [not defined] from bone marrow and spleen. HU rapidly induced a macrocytic hypochromic anemia and altered white blood cell kinetics, assocd. with myelosuppression, defined as reduced marrow organ cellularity and induction of splenic extramedullary hematopoiesis. Compared to HU, TX and DX induced fewer changes in peripheral blood indexes and CFU-GM and BFU-E per hematopoietic organ. In vitro human and murine marrow CFU-GM and BFU-E colony formations were assayed in the presence of increasing concns. of HU, DX, or TX (0, 1, 10, 50, 100, and 200 .mu.M). HU inhibited colony formation more than either DX or TX. These studies suggest that the novel ribonucleotide reductase inhibitors TX and DX may provide an effective alternative to HU in HIV-1 therapy because they cause less hematopoietic toxicity.

CC 1-2 (Pharmacology)
AB The mechanism for formation of high-affinity binding of 1-(2,6-dichlorobenzylidene-amino)-3-hydroxyguanidine (guanoxabenz) to .alpha.2-adrenoceptors was studied in particulate fractions from the rat spleen. The proportion of apparent high vs. low-affinity .alpha.2-adrenoceptor binding sites increased with increasing incubation time and was also augmented by Mg2+ ions. The formation of high-affinity guanoxabenz binding seemed to be inhibited by a series of N-hydroxyguanidine analogs to guanoxabenz, as well as by a series of metabolic inhibitors that included allopurinol, 1-chloro-2,4-dinitrobenzene, 5,5'-dithiobis-(2-nitrobenzoic acid), cibacron blue, phenyl-p-benzoquinone, didox, and ***trimidox*** . The formation of guanoxabenz high-affinity binding was also inhibited in a time- and concn.-dependent fashion by preincubating the membranes with the LW03 N-hydroxyguanidine analog of guanoxabenz. Moreover, when the spleen membranes were extensively washed for 30 min with buffers at 25.degree., the guanoxabenz high-affinity binding disappeared. However, when these washed membranes were supplemented with xanthine, the apparent affinity of guanoxabenz increased four- to five-fold. Taken together, all data were compatible with the theory that the formation of high-affinity binding was dependent on the generation of a guanoxabenz metabolite that showed an approx. 100-fold greater affinity for the .alpha.2-adrenoceptors than guanoxabenz itself. Because the most potent blocker of the formation of high-affinity binding was allopurinol (apart from some N-hydroxyguanidine analogs to guanoxabenz) and since the activity could be restored with xanthine, a likely candidate responsible for the metabolic activation is xanthine oxidase.

AB Ribonucleotide reductase is the rate limiting enzyme of de novo DNA synthesis; its activity is significantly increased in tumor cells related to the proliferation rate. Therefore the enzyme is considered to be an excellent target for cancer chemotherapy. In the present study we tested the in vitro and in vivo antitumor effects of a drug combination using ***trimidox*** (3,4,5-trihydroxybenzamidoxime), a novel inhibitor of ribonucleotide reductase with adriamycin, a widely used anticancer drug. This combination was selected because adriamycin generates free radicals being responsible for cardiotoxic side effects, ***trimidox*** has been shown to be a good free radical scavenger. The in vitro cytotoxic effect of the drug combination was examd. in L1210 mouse leukemia cells employing a MTT chemosensitivity assay. Incubation of these cells with adriamycin and ***trimidox*** together yielded less than additive cytotoxic effects compared to either drug alone. These effects were not caused by the involvement of p-glycoprotein mediated drug efflux. However, when the effect of ***trimidox*** and adriamycin in combination was examd. in L1210 leukemia bearing mice antitumor effects of adriamycin could be enhanced by the presence of ***trimidox*** . Our data indicate, that the in vivo combination of adriamycin together with ***trimidox*** might be beneficial for the treatment of malignancies.

AB ***Trimidox*** (3,4,5-trihydroxybenzamidoxime) has been shown to reduce the activity of ribonucleotide reductase with accompanied growth inhibition and differentiation of normoblast cells. Hydroxyurea (HU) is the only ribonucleotide reductase inhibitor in clin. use for the treatment and management of sickle cell anemia, since this compd. increases fetal Hb (Hb F) prodn.: a potent inhibitor of sickle Hb (Hb,SS) polymn. However, the main limitations of HU is its lack of potency, myelosuppression and short half life. These studies investigated the effects of ***trimidox*** on the induction of Hb and F-cells prodn. in K562 erythroleukemia cells. Our study reveals that ***trimidox*** exhibits concn. dependent inhibitory effect on K562 cells with increase in benzidine pos. normoblasts and F-cells prodn. as well as morphol. changes typical of erythroid differentiation. These findings provide the first evidence that the growth inhibitory differentiation of cells induced by ***trimidox*** enhance Hb and F-cells prodn. (c) 1998 Academic Press.

AB Ribonucleotide reductase, a key enzyme in deoxyribonucleotide synthesis, is an important target for cancer chemotherapy. Drugs that inhibit its individual components may act synergistically to block DNA synthesis. Prior work has established that gallium inhibits the R2 subunit of ribonucleotide reductase. We show that gallium acts synergistically with the ribonucleotide reductase inhibitors gemcitabine and hydroxyurea to inhibit the proliferation of CCRF-CEM cells. In contrast, combinations of gallium with the ribonucleotide reductase inhibitors amidox, didox, or ***trimidox*** produced antagonistic effects on cell growth. Spectroscopy anal. revealed that as a result of their metal-binding properties, amidox, didox and ***trimidox*** formed complexes with gallium, thus negating potential synergistic actions. Our results have important implications in the design of clin. trials using these ribonucleotide reductase inhibitors in combination.

AB The DNA-protective activity of hydroxyurea (HU) and novel ribonucleotide reductase (RR) inhibitors amidox (AX), didox (DX) and ***trimidox*** (TX) was examd. using hydrogen peroxide as the DNA-damaging agent. The exposure of superspiralized plasmid DNA mols. (pBR 322) to H2O2 under precisely defined in vitro conditions initiates a change in DNA topol. (DNA form I relaxes to DNA form II). This electrophoretically monitored change in the plasmid DNA topol. is related to the induction of ss-DNA breaks and corresponds with DNA exposition to free radicals. The inhibition of DNA relaxation (the prevention of DNA damage induced by hydrogen peroxide) depended on the free radical scavenging capacity of the drugs investigated. HU exerted DNA protective activity at a concn. of 4 mM, AX at concn. of 1 .mu.M, TX at a concn. of 5 .mu.M and DX at a concn. of 25 .mu.M (the free radical scavenging activity increases from HU to AX in following manner: HU .mchlt. DX < TX < AX). It can be concluded that the new synthetic RR-inhibitor AX which is being investigated at the preclin. level as a potential anti-cancer drug possess the highest capacity for scavenging of free radicals.

However, when the effect of ***trimidox*** and adriamycin in combination was examd. in L 1210 leukemia bearing mice, antitumor effects of adriamycin could be enhanced by the presence of ***trimidox*** . Animals were treated on day two after tumor cell injection with 5 mg/kg

adriamycin and received 250 mg/kg ***trimidox*** on days 2, 3 and 4. Mice treated with adriamycin or ***trimidox*** alone yielded a 41 and 30% increase in life span, resp. However, animals which were treated with both drugs, showed a 60% increase of their life span. Our data indicate, that in vitro results of drug combinations should be interpreted with extreme caution and suggest that the in vivo combination of adriamycin together with ***trimidox*** might be beneficial for the treatment of malignancies.

AB Ribonucleotide reductase inhibitors (RRIs) have been recently shown to inhibit retroviral replication. We examd. a new series of RRIs, 3,4-dihydroxybenzohydroxamic acid (Didox) and 3,4,5-trihydroxybenzohydroxamidoxime (***Trimidox***) for their ability to alter disease progression in murine acquired immunodeficiency syndrome (MAIDS), both alone and in combination with 2',3'-dideoxyinosine (ddI). MAIDS disease was induced by inoculation of female C57BL/6 mice with the LP-BM5 murine leukemia virus (MuLV) and disease progression characterized by extensive peripheral lymphadenopathy and splenomegaly. Efficacy of treatment with these drugs was based upon their ability to influence survival and disease pathophysiol. by monitoring the development of splenomegaly. Toxicity was detd. by changes in body wt., total peripheral white blood cell count and hematocrit. Didox or ***trimidox*** monotherapy was assocd. with increased survival and decreased disease pathophysiol., with no apparent toxicity. Combined with ddI, their ability to reduce development of viral induced splenomegaly was enhanced compared to ***trimidox*** , didox or ddI alone. These results demonstrate RRIs have potent activity in reversing the disease manifestations characteristic of MAIDS. Further studies are warranted to det. human clin. efficacy.

AB Oxidative stress activates the NF-kappa B/Rel transcription factors which are involved in the activation of numerous immunoregulatory genes and the human immunodeficiency virus type 1 (HIV-1) long terminal repeat (LTR). In the present study, we exmd. the effects of established and novel compds. including antioxidants, ribonucleotide reductase inhibitors, and iron chelators on NF-.kappa.B activation and HIV LTR-mediated gene expression induced by TNF-.alpha.. N-Acetylcysteine (NAC), pyrrolidinedithiocarbamate (PDTC), and ***Trimidox*** (TD) at various concns. inhibited TNF-.alpha.-induced NF-.kappa.B binding in Jurkat cells. Pretreatment of cells with these compds. prior to stimulation prevented I.kappa.B.alpha. degrdn. Phosphorylation of I.kappa.B.alpha., a prerequisite for its signal-induced degrdn., was abrogated in these cells, indicating that oxidative stress is an essential step in the NF-.kappa.B activation pathway. On the other hand, iron chelators desferrioxamine, pyridoxal isonicotinoyl hydrazone (PIH), and salicylaldehyde isonicotinoyl hydrazone (SIH) showed no inhibition of TNF-.alpha.-induced NF-.kappa.B DNA-binding activity. Synergistic induction of HIV-1 LTR-mediated gene expression by TNF-.alpha. and the HIV-1 transactivator Tat in Jurkat cells was significantly suppressed in the presence of NAC and TD, but not PDTC. The inhibition of NAC and TD on LTR-directed gene expression was diminished when NF-.kappa.B-binding sites in the LTR were deleted, indicating that these compds. affected the NF-.kappa.B component of the synergism. Iron chelators PIH and SIH also showed some inhibitory effect on LTR-mediated gene activation, presumably through an NF-.kappa.B-independent mechanism. These expts. demonstrate that TD, at concn. 50 times lower than the effective concn. of NAC, potently inhibits NF-.kappa.B activity and suppresses HIV LTR expression.

AB Amidox (AX), didox (DX) and ***trimidox*** (TX), compds. synthesized as new ribonucleotide reductase inhibitors, have been investigated by UV spectrophotometry, polarog. HPLC. The expts. were performed at various pH values. The changes in UV absorption of the compds. studied were recorded and it was demonstrated that these changes are related to the pH and to structural features of the investigated mols. Only amidox and ***trimidox*** were reduced during polarog. expts. in Britton-Robinson buffer. The redn. of both compds. proceeded in 2 1-electron steps in acid solns. One 2-electron diffuse irreversible wave was obsd. at basic pH values. The values of the half-wave potential became more neg. with increasing pH values. HPLC assay also showed changes in the retention of compds. investigated, particularly when the pH of the mobile phase was close to the dissocn. const. of the particular drug. The changes of physicochem. properties detected by the methods are related to different chem. structures (the most significant changes were obsd. in alk. pH).

AB Ribonucleotide reductase is the rate limiting enzyme of deoxynucleoside triphosphate synthesis and is considered to be an excellent target of cancer chemotherapy. ***Trimidox*** , a newly synthesized compd., inhibits this enzyme and has in vitro and in vivo antitumor activity. As ***trimidox*** was able to upregulate the expression of the transferrin receptor in HL-60 human promyelocytic leukemia cells, the authors have now investigated the capability of ***trimidox*** to interfere with iron metab. The authors show by photometric and polarog. methods that ***trimidox*** is able to form an iron complex. However, its cytotoxic action cannot be circumvented by addn. of iron-satd. transferrin or iron-ammonium citrate, indicating that the iron complexing capacity is not responsible for the mechanism of action of this compd. When HL-60, K562 or L1210 leukemia cells were incubated with the ***trimidox*** -iron complex itself, the authors could observe increases of the 50% growth inhibitory capacity of the complex in comparison with ***trimidox*** alone. The authors conclude that ***trimidox*** is able to form an iron complex, but in contrast to other agents, the anticancer activity cannot be contributed to this effect alone. Further studies will have to elucidate the mol. mechanism of action of this new and promising anticancer agent.

AB Increased ribonucleotide reductase (RR) activity has been linked with malignant transformation and tumor cell growth. Therefore, this enzyme is considered to be an excellent target for cancer chemotherapy. The authors have examd. the effects of a newly patented RR inhibitor, ***trimidox*** (3,4,5-trihydroxybenzohydroxamidoxime). ***Trimidox*** inhibited the growth of human promyelocytic leukemia HL-60 cells with an IC50 of 35 .mu.mol/L. Incubation of HL-60 cells with 50 .mu.mol/L ***trimidox*** for 24 h decreased deoxyguanosine triphosphate (dGTP) and deoxycytidine triphosphate (dCTP) pools to 24% and 39% of control values, resp. Incubation of HL-60 cells with 20 to 80 .mu.mol/L ***trimidox*** even up to a period of 4 days did not alter the distribution of cells in different phases of cell cycle. Sequential incubation of HL-60 cells with ***trimidox*** (25 .mu.mol/L) for 24 h and then with 10 .mu.mol/L tiazofurin (an inhibitor of inosine monophosphate dehydrogenase) for 4 days produced synergistic growth inhibitory activity, and the cell no. decreased to 16% of untreated controls. When differentiation-linked cell surface marker expressions were detd. in cells treated with ***trimidox*** and tiazofurin, a significantly increased fluorescence intensity was obsd. for the CD 11b (2.9-fold), CD 33 (1.9-fold), and HLA-D cell surface antigens. Expression of the transferrin receptor (CD71) increased 7.3-fold in cells treated with both agents, compared with untreated controls. The results suggest that ***trimidox*** in combination with tiazofurin might be useful in the treatment of leukemia.

AB ***Trimidox*** (3,4,5-trihydroxybenzamidoxime), a newly synthesized analog of didox (N,3,4-trihydroxybenzamide) reduced the activity of ribonucleotide reductase (EC 1.17.4.1) in exts. of L1210 cells with an IC50 of 5 .mu.M, whereas hydroxyurea, the only ribonucleotide reductase inhibitor in clin. use, exhibited an IC50 of 500 .mu.M. Ribonucleotide reductase activity was also measured in situ by incubating L1210 cells for 24 h with ***trimidox*** at 7.5 .mu.M (a concn. that inhibited cell proliferation by 50%) or at 100 .mu.M for 2 h; these concns. resulted in a decrease in enzyme activity to 22% and 50%, resp., of the control value. ***Trimidox*** and hydroxyurea were cytotoxic to L1210 cells, with IC50 values of 7.5 and 50 .mu.M, resp. Vs. ribonucleotide reductase, ***trimidox*** and hydroxyurea had IC50 values of 12 and 87 .mu.M, resp. ***Trimidox*** concn.-dependently increased the life span of mice bearing L1210 leukemia. The antitumor activity appeared more pronounced in female mice than in male mice. These findings suggest that ***trimidox*** is a new and potent inhibitor of ribonucleotide reductase and that it is a promising candidate for the chemotherapy of cancer in humans.

AB The development of a reliable and simple system for evaluating compds.

that could prevent activation of latent HIV would allow us to devise new therapeutic approaches. These compds. could eventually be used in combination with drugs that are effective against acute and chronic infections. The OM-10.1 cell line is a chronically infected clone which remains CD4+ until HIV-1 activation with tumor necrosis factor-.alpha.. A variety of compds. are known to have antiviral properties against either acutely or chronically infected cells were evaluated for their ability to inhibit HIV induced expression in these cells. The authors also examd. the effect of several compds. that interact with biochem. pathways that may interfere with or enhance the reactivation process. These included nucleoside analogs, cytokines, steroidal and non-steroidal anti-inflammatory agents, polyoxometalates, a TAT inhibitor, various natural products (including nerve growth factor, N-acetyl-L-cysteine, taxol, and interferons), TIBO, porphyrins, and various oligomers. CD4 cellular expression and supernatant reverse transcriptase activity were quantitated as markers of induced viral expression. Among several compds. evaluated, 3'-fluoro-3'-deoxythymidine (FLT), interferon .gamma., Ro 5-3335 (a TAT inhibitor) and desferrioxamine were modest and selective inhibitors of HIV-1 activation.
